ABSTRACT

Background: Acute lymphoblastic leukemia (ALL), the most common childhood cancer with a peak incidence in children from 2-5 years old, might be associated with poor prognosis and resistance to therapy in specific cytogenetic backgrounds. FoxO3a, a member of the forkhead class ‘O’ (FoxO) transcription factors, is a main downstream target of PI3K/AKT pathway which regulates different variety of biological processes and is overactivated in several human cancers. We aimed to evaluate the aberration of the FoxO3a gene in mRNA level in childhood ALL and compare them with healthy controls.

Methods: Real-time quantitative RT-PCR (qRT-PCR) was used to detect FOXO3a expression in 30 new cases of pediatric ALL and 30 age- and sex-matched healthy children as the control group.

Results: the expression level of the FoxO3a gene was significantly lower in ALL patients compared to healthy controls (P<0.0001), while no difference was observed between the two sub-types B- and T-ALL.

Conclusion: Our study suggested that decreased FoxO3a expression may play an important role in the development of pediatric ALL. FoxO3a could be considered as a molecular target of therapy in ALL malignancy.

Introduction

Leukemia is a malignancy of hematopoietic cell populations that include diverse and biologically distinct sub-groups.¹ Acute Lymphoblastic Leukemia (ALL) is one of the four major types of leukemia which is common in both children and adolescents; however, it is the most common pediatric malignancy diagnosed in children younger than 20 years.²,³ Regarding the World Health Organization (WHO) definition, ALL is categorized in B-Lymphoblastic Leukemia (B-ALL) and T-Lymphoblastic Leukemia (T-ALL), originated from B- and T-Lineage lymphoid precursor cells, respectively.⁴

The disease pathogenesis results from blockade at any stages of normal lymphoid differentiation due to uncontrolled proliferation of lymphoid cells.⁵ Lack of enough information on the precise origin of the leukemic cells, biological behavior of the hematopoietic primitive cells, mechanisms that damage the earliest steps of the lymphoid development as well as high genetic heterogeneity make ALL a condition full of ambiguity.⁶,⁷

From genetic point of view, proto-oncogenes and tumor suppressor genes are the most important genes involved in leukemogenesis,⁸,⁹ which their alterations disrupt normal regulatory processes such as self-renewal, proliferation, differentiation and apoptosis in target cells.¹⁰

FoxOs (Forkhead box, class O) transcription factors function as a tumor suppressor gene and are important for stem cell maintenance.¹¹ They are key regulators of the cellular differentiation, growth, survival, cell cycle, metabolism, and cellular stress.¹² FoxO1, FoxO3a,
FoxO4 and FoxO6 are four members of the FoxO transcription factor family in humans.3 FoxO3a expresses in various tissues including B- and T-lineage cells.12,14 Transcriptionally, FoxO3a activates several target genes such as apoptosis-related genes (Bim, Fasl, TRAIL, PUMA) and cell cycle inhibitor genes (P27, P21).15 FoxO3a is an important target of PI3K/AKT signaling pathway, which is hyperactivated in various type of cancers.16 Hyperactivation of this pathway in leukemia leads to inactivation of FoxO3a in leukemic cells and eventually tumor growth.17 This evidence emphasize on FoxO3a as a tumor suppressor role gene. Moreover, overexpression of FoxO3a in B and T cell lines induces cell cycle arrest in G1 phase and triggers apoptosis by induction of the cell cycle inhibitor protein, P27, and pro-apoptotic molecules FasL and Bim, respectively.14

So far, few reports have been published concerning the role of FoxO3a in childhood ALL. The expression profile of FoxO3a in childhood ALL has not yet been reported. Thus, we aimed to analyze the mRNA expression level of FoxO3a in children with ALL among the population in southern Iranian.

Patients and Methods
Patient Characteristics and Sample Collection
30 children aged 2-17 years referred to Amir Oncology Hospital, Shiraz, Iran, and diagnosed as new cases of acute lymphoblastic leukemia were included in the study. 30 healthy age- and sex-matched children without a history of any malignancies were enrolled as the control group. The accuracy of the diagnosis was confirmed using immunology and cytogenetic tests as well as monitoring the morphology of the cells. Patients who met the following criteria were excluded; a) age more than 20 years, b) presence of other hematological disorders, history of other malignancies or relapsed ALL, and c) patients under chemotherapy or radiotherapy. The study design was approved by the Ethics Committee of Islamic Azad University, Arsanjan Branch and written informed consent was obtained from the parents of all children who participated in the study.

RNA Extraction and Real-Time PCR Analysis
To determine the expression level of FoxO3a gene, as a candidate gene involving in the pathogenesis of ALL, total RNA from fresh blood samples was isolated using RNX-Plus solution (CinnaGen, Iran) according to the manufacturer’s instructions and cDNA was prepared using RevertAid first-strand cDNA synthesis kit (Thermo Scientific Fermentas, USA) following the manufacturer’s instructions. All primer pairs used in this study were designed by Allele ID v7.8 software. Primers were specific for mRNA and did not amplify genomic DNA. The primer sequences were as follows: Forward, 5-CCGACAACGGGCTC ACTCT-3 and reverse, 5-GGACCGCATGAATCG ACTAT-3 for FoxO3a gene; and forward, 5-CCCGAAACGCCGAATATAAT-3 and reverse, 5-CTGGACTGTCTTCAC TCTTG-3 for TBP gene. The cDNA were subjected to quantitative RT-PCR (qRT-PCR) analysis using a Rotor-Gene Q 2plex HRM Platform real-time PCR system (Corbett Life Science) to evaluate the relative expression levels of FoxO3a and TBP (as an endogenous control gene). Each 15μl reaction volume contained 7.5μl of 2x Evagreen mastermix (Yekta Tajhiz Azma, Iran), 1.25μl of cDNA, and 0.4μl (10pm) of each pair of oligonucleotide primers. All reactions were done in duplicate. The PCR cycling began with an initial step of 95˚C for 15 min followed by 35 cycles of 95˚C for 25 sec, 54˚C for 20 sec and 72˚C for 20 sec; then a melting curve analysis was performed. The threshold cycle (CT) values were determined using Rotor-gene Q sequence detection system. The relative expression levels of the target gene were normalized to that of the endogenous control gene, TBP. The data were analyzed using the comparative threshold cycle $(2^{-\Delta\Delta CT})$ method.

Statistical Analysis
Chi-square test was used to compare the nominal variables among ALL patients (cases) and healthy children (controls). Data were analyzed with GraphPad Prism statistical software (La Jolla, USA) using unpaired t-test to compare the difference in gene expression between cases and controls. P value of <0.05 was considered statistically significant.

Results
Demographic features of ALL cases and controls are shown in table 1. Among them, 9 (30%) patients were diagnosed with T-cell ALL, and the rest (70%) with B-cell precursor ALL. 36.7% of all patients were female, and 63.3% were male. Although there was not a significant difference in frequency of blood groups between the patients and control group, the frequency of blood groups B and O were slightly higher among cases compared to the control group (table 2).

healthy subjects. The Foxo3a mRNA expression level was significantly lower in ALL patients compared with the control group (P<0.0001). Quantitative RT-PCR showed more than 3-fold downregulation of Foxo3a gene (figure 1).

Furthermore, we analyzed the mRNA expression level of Foxo3a in 21 B-ALL patients compared with 9 T-ALL patients. Results showed more reduction in the FoxO3a expression, but this difference was not statistically significant between the two groups (P=0.23) (figure 2).

**Discussion**

ALL accounts for about 78% of all childhood leukemias. Poor prognosis and resistance toward treatment are the key characteristics which represent some cases of ALL as an incurable cancer. Poor prognosis for ALL reflects in part the lack of knowledge about the tumor basic biology. Present study for the first time, best of our knowledge, demonstrates a new molecule that its aberrant expression plays an important role in ALL pathogenesis among children. Decrease in mRNA level of the FoxO3a gene, as shown in our study confirmed the role of this transcription factor as a tumor suppressor gene in pathogenesis of the pediatric ALL. The result of our study was similar to those for breast, ovarian, prostate and gastric cancers. In all these studies, it has been shown that overexpression of FoxO3a inhibits cell proliferation and then prevents tumor progression.

It has been demonstrated that PI3k/AKT signaling pathway is a central circuit in pathogenesis of acute leukemia. Constitutive activation of this pathway has been demonstrated as a key pathogenic mechanism involved in AML development. Similar to AML, PI3K/AKT activation is frequently found in B-ALL; however, its alterations is predominant in T-ALL in comparison with other leukemias. One of the most favorable downstream effects of the activated PI3K/AKT pathway includes inactivation of FoxO3a through phosphorylation and restoration of this transcription factor. Here, we also suggest the PI3k/AKT signaling pathway as a molecular mechanism which controls cell growth, apoptosis, development and progression of ALL via downregulation of FoxO3a.

One of the previous studies on the chemoresistance of T-ALL cells have shown the cytoplasmic localization of FoxO3a; therefore these cells inactivate FoxO3a in order to escape TRAIL and Noxa-induced apoptosis. FoxO3a deficient mice showed reduced number of Pre-B cells and re-circulating B cells in bone marrow and peripheral blood, so FoxO3a makes a unique contribution to B cell development. Conditional deletion of FoxO3a in mice affects lymphoproliferation and finally widespread organ inflammation. Mice with conditional deletion of FoxO1, FoxO3a and FoxO4 showed abnormalities in lymphoid development resulting in a long term defect in repopulation activity of the bone marrow stem cells.

In summary, the current study provided information, for the first time, on essential role of FoxO3a in development of ALL disease. Understanding the precise role of FoxO3a in ALL will not only increase our knowledge of the biology of this malignancy but its upregulation may also allow development of a novel therapeutic strategy.
