ABSTRACT

Prostate cancer (PCa) is the most common type of cancer among men over 60 years old. The aggressiveness and mortality of PCa can be correlated with obesity. Adipose tissue-derived cytokines such as adiponectin may explain the correlation between PCa and obesity. Since the correlation between adiponectin and aggressive PCa is still not fully evaluated, we aimed to investigate the probable role of adiponectin in PCa. Adiponectin is considered as a link between obesity, insulin resistance and diabetes. On the other hand, adiponectin is a key mediator of systemic insulin sensitivity and glucose homeostasis. Moreover, low level of adiponectin is associated with inflammation and angiogenesis. These processes could promote tumor growth. Special effects of adiponectin are mediated via adenosine monophosphate-activated protein kinase (AMPK). AMPK activation inhibits growth of androgen-independent and androgen-sensitive PCa cell lines. Moreover, c-Jun N-terminal protein kinase (JNK) and Signal transducer and activator of transcription 3 (STAT3) signaling pathway are known as adiponectin’s mediators on the metabolic syndrome and cancer. Furthermore, adiponectin acts as a tumor suppressor gene via inhibition of Epithelial-to-mesenchymal Transition (EMT) of PCa cells, but it is down regulated through hypermethylation of promoter gene in PCa cells. Therefore, according to the results of these studies, decreased concentration of adiponectin was associated with increased risk of PCa. It seems that hypoadiponectinemia may act as a promising biomarker for detection and diagnosis of PCa.

Introduction

One of the most fatal diseases in human beings is cancer which leads to an annual death of 30000 people in Iran.1,2 The most common type of cancer among men older than 60 years is prostate cancer (PCa).3 PCa is the second leading cause of cancer death among American men. The highest incidence of PCa is in the United States, Canada, and northwestern Europe, but less common in Asian countries and South America so that 9% of all cancer-related deaths are among men within the European Union.4 Since androgens play a main role in smooth muscle proliferation associated with the development of PCa, men with increased risk of PCa may show higher risk of cardiac disease.4 Patients with PCa are often treated with androgen deprivation therapy (ADT).5 Tumor biomarkers like prostate specific antigen (PSA), acid phosphatase (ACP) and prostatic acid phosphatase (PAP) can be used for early diagnosis, staging and monitoring of the disease.3 Decreasing level of prostatic biomarkers in serum of PCa patients could serve as an indicator of response to the treatment.3 Nowadays, several risk factors contributing to the development of PCa have been identified.4 Moreover, numerous studies have shown that the aggressiveness and mortality of PCa could be correlated with obesity.6 Adiponectin is considered as a potential biological link between obesity and PCa, but there is paucity of epidemiological data confirming this association.7 Therefore, the aim of the current review was to assess the relationship between obesity, adiponectin, and PCa.

Adiponectin

Adiponectin is a product of the APM1 gene8 located on
chromosome 3q27.9. It is a 244 aminoacid polypeptide with 30 KDa molecular weight which is widely synthesized and secreted by adipose tissues. Studies have shown a link between obesity, insulin resistance and diabetes which play an important role in diabetes and cardiovascular disease.

Serum concentrations of adiponectin is in the range of 2 to 20 mg/L. The mean level of adiponectin concentration is 1000 times higher than leptin and cortisol level and 100000 times higher than cytokines like interleukin-6 and TNF-α. The level of adiponectin in men is about 40% lower than in women. It seems that it is due to androgens, since androgens have an inhibitory effect on adiponectin secretion.

Adiponectin contains three domains including a signal peptide, a collagen-like motif and a globular domain. Moreover, circulating adiponectin exists in at least two forms; low molecular weight (LMW) oligomer that is a hexamer of two trimers and high molecular weight (HMW) oligomer containing four- six trimmers. Plasma adiponectin concentrations are inversely correlated with fasting plasma insulin levels.

Adiponectin Receptors
Adiponectin acts via binding to main receptors; adiponectin receptor 1(AdipoR1) and adiponectin receptor 2 (AdipoR2). AdipoR1 and AdipoR2 encoding genes are located on chromosomes 1p36.13-q41 and 12p13.3, respectively. Expression of these receptors (AdipoR1 and AdipoR2) has been detected in monocytes, and megakaryocyte cell lines.

Increased risk of advanced disease and death in PCa patients. Several factors can increase the risk of tumor initiation and progression. Environmental factors such as diet with higher content of saturated fat and obesity itself can be connected to PCa. The consumption of fat is concordantly correlated to PCa mortality rate. It seems that high level of dietary fat stimulates PCa cells proliferation. Obesity and diabetes together lead to hyperinsulinemia and may promote the risk of PCa development. Insulin resistance can alter the risk of PCa via diverse biologic pathways such as obesity-sex hormone pathway and non-obesity-related pathways. Insulin resistance can increase the risk of PCa via non-obesity-linked mechanisms like inflammation, oxidative stress, and apoptosis. Therefore, it seems that many factors such as insulin resistance and obesity may be related to PCa.

Obesity causes increased level of free Insulin-like growth factor (IGF-1) which stimulates growth of prostate cell lines in vitro. Moreover, obesity is related to advanced stage of PCa in humans and leads to elevated level of serum interleukin-6 in adipose tissues. PCa cell line and PCa patients have been shown to be capable of increased production of IL-6 and IL-6 receptor. Circulating level of IL-6 is associated with progression of metastatic disease. In addition, human PCAs expressed high amounts of leptin receptor. Moreover, studies have shown that the relationship between leptin and PCa is contradictory. Some studies have found a positive correlation between serum leptin level and PCa risk, but others have found no association. Adipose tissue-derived cytokines like adiponectin could explain the association between PCa and obesity. Adipokines may provide a molecular mechanism whereby obesity exerts its effects on prostate tumor biology. It seems that obesity affects prostate tumor biology via exposing of prostate cells to circulating adipokines. Adiponectin plays a main role as a molecular basis for the association between obesity and PCa.
Adiponectin also increased sensitivity of insulin in various stromal and epithelial cells. It seems that adiponectin has potent insulin-sensitizing actions. On the other hand, adiponectin is a key mediator of systemic insulin sensitivity and glucose homeostasis. The main metabolic effects of adiponectin are suppression of hepatic glucose production and modulation of suppressing inflammatory responses in other cell types including macrophages. Another study reported that the anti-neoplastic activity of adiponectin may be explained possibly by decreasing insulin resistance and hyperinsulinemia.

Low levels of adiponectin could result in higher inflammatory states and angiogenesis. These processes promoted tumor growth. Another study reported that the effect of adiponectin on neovascularization remains contradictory, so that it has both pro and anti-angiogenic effects. Moreover, adiponectin mRNA expression is decreased in adipose tissues. This change is related to a higher risk of diabetes evolution. Therefore, it is hypothesized that decreased level of adiponectin may underlie the association between PCa and obesity/insulin resistance.

Another study showed that there is inverse relationship between metformin and serum prostate-specific antigen in PCa, independent of other anti-hyperglycemic medications. Metformin improves PCa recurrence and survival rate. Metformin as an anti-diabetic drug caused activation of AMPK and inhibited growth of PCa cells. Antineoplastic mechanism of metformin can be due to inhibition of mTOR in the PI3K/AKT/mTOR pathway. Moreover, metformin has a main role in decreasing level of gene expression involved in mitosis. Therefore, it seems that metformin therapy leads to a better prognosis in patients with PCa.

Conclusion
According to the ample studies in the literature, decreased concentration of adiponectin was associated with increased risk of PCa. Therefore, it seems that hypoadiponectinemia may be a promising biomarker for early detection of PCa.
