2Kerman Medical University, Kerman, Iran

ABSTRACT

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive malignancy of mature B lymphocytes. It is known as a heterogeneous disease with variable therapeutic responses and alternative therapies. Morphological and immunophenotypical evaluation of the biopsy specimens can help diagnose DLBCL.

Methods: In the current study, 44 patients were chosen from Shaheed Sadoghi Hospital (2010–2013), central Iran. Immunohistochemical method was used for detecting biomarkers such as CD2, CD3, CD20 and CD45.

Result: In this study, 54.5% of the patients were men and 45.5% were women. Most of the patients were 40-50 years old. Moreover, 10 (22.7%) patients had lymph node metastasis and 6 (13.6%) patients had stomach involvement. Positive expression of CD45 and CD20 biomarkers were expressed in 100% and 97.7% of the patients. Positive expression of CD3 and CD2 was expressed in 40.9% and 81.8% of the patients, respectively. C-expression of CD45 and CD20 biomarkers was seen in 43 patients. Moreover, there was no relation between biomarkers and sex and age (P>0.05).

Conclusion: The result of this study showed that high number of CD45 and CD20 have been seen in Iran’s population. Moreover expression of CD20 and CD45 is different as compared with other populations. It seems that these differences can be due to ethnic groups and nature of malignant cells.

Introduction

Diffuse large B-cell lymphoma (DLBCL) is an aggressive malignancy of mature B lymphocytes.1,2 It is known as a heterogeneous disease3 with variable therapeutic responses and alternative therapies.4 The causes of diffuse large B cell lymphoma are not well understood yet.5 Following nodular lymphocyte predominant HL, diffuse large B-cell lymphoma (DLBCL) can be observed as one of the most common lymphoid malignancy in adults diagnosed on basis of morphology and immunophenotype.6 DLBCL accounts for 30–40% of adult non-Hodgkin lymphomas.7 The peak occurrence of diffuse large B-cell lymphoma (DLBCL) arises in the seventh decade of life.8 The first sign of this disease is rapidly growing mass, fever, weight loss, and night sweats.9 Diffuse large beta cell lymphoma disorder manufactured of a clinically and pathologically heterogeneous group of lymphoproliferative malignancies, most of which are B-cell origin.8 Morphological and immunophenotypical evaluation of the biopsy specimens can help to diagnosis of DLBCL.10 Diffuse large B cell lymphoma includes three variants

...in term of morphology. Centroblastic, Immunoblastic and anaplastic. Most DLBCL cases are centroblastic. Each has a diverse clinical presentation and prognosis. However, the usual treatment for each of these is chemotherapy, often in combination with an antibody targeted at the tumor cells. The disease is treatable in most patients, but fewer than half of them attain a durable remission. CD3 is a marker for T cells and natural killer cells. It is specific for T-cell derivation. CD2 is also expressed by T and natural killer (NK) cells and has been reported in T/NK cell lineage neoplasms as well as in immature B-lymphoblastic and myeloid leukemias. CD45 (lymphocyte common antigen) is a receptor-linked protein tyrosine phosphatase and expressed on all leucocytes. It plays a significant role in the action of these cells. CD20 is an activated glycosylated phosphoprotein. It is expressed on the surface of B cells beginning at the pro-B phase (CD45R+, CD117+). We aimed to evaluate CD markers such as CD45, CD20, CD3 and CD2 in patients with diffuse large B cell lymphoma in Yazd city, central Iran.

Materials and Methods

In this study, 44 patients were enrolled from Shaheed Sadoghi Hospital, Yazd, central Iran during 2010-2013. The specimens were conserved in formalin. Following fixation, the specimens were embedded on wax paraffin and sliced to 4 μm in thickness for staining. The hematoxylin and eosin staining method was used to stain the tissue sections. In immunohistochemical method, Endogenous peroxidase was blocked by 3% hydrogen peroxide in methanol for 10 minutes at room temperature. Heat-induced epitope retrieval was done by heating these sections in citrate buffer (pH 9.0) using the microwave technique. After cooling, the sections were exposed with primary antibody (table 1).

Then, the specimens were exposed to Horseradish peroxidase rabbit anti-mouse IgG for 30 min and incubated with 3,3-diamino-benzidine tetrahydrochloride. The sections were counterstained with hematoxylin and rinsed in tap water, followed by immersing in graded alcohol, xylene and finally mount. Negative control was done by displacement of the primary antibody with fetal bovine serum in each series.

Result

In our study, the mean±SD age of the patients was 55.8±9.5 years. 27 (61.2%) out of 44 patients were younger than 60 years old. 54.5% of the patients were men. 10 (22.7%) patients had lymph node metastasis. Table 2 shows the primary tissue involvement. In this study CD45 was expressed in 100%, CD20 in 97.7%, CD3 in 40.9%, and CD2 in 81.8, respectively. Table 3 shows expression of these biomarkers in the patients. Table 4 shows co-expression of Biomarkers. No relation between percentage of expression of biomarkers with sex was observed (P>0.05).

Discussion

In the present study, immunohistochemical staining of the specimens with DLBCL were positive for CD45 and CD20 in almost all of the patients and less than half expressed CD3 and CD2. Asano and colleagues reported negativity for CD20 and CD3 in their patients with DLBCL. Kevin and co-workers reported that some cases of DLBCL with an anaplastic morphology may be rich in...

Reed-Sternberg like cells and thus simulate lymphocyte-depleted classical Hodgkin lymphoma. However, in contrast to Hodgkin lymphoma, these neoplastic cells were uniformly positive for both CD20 and CD79a antigens and were negative for CD15. Therefore, they reported that the majority (65-85%) of the cases of DLBCL in their study were of B-cell type.31

Stein et al. reported that CD30 which was constantly expressed in Reed-Sternberg cells, is also expressed by a subset of DLBCL patients.32 In another study, aberrant expression of a single T-cell-associated antigen (CD5) on specimens of DLBCLs was reported.20 The researchers also reported aberrant co-expression of 2 T-cell-associated antigens; CD2 and CD7 in patients with diffuse DLBCL. In a study by Toyama et al., flowcytometric immunophenotyping of the DLBCL cases were negative for CD2, CD3 and positive for CD20.21 Asano et al. in another study reported that CD30 and CD45 were positive in DLBCL (anaplastic variant), but negative for CD3, CD10, CD20, CD15.18

The result of this study showed high percentage of CD45 and CD20 seen in Iran’s positivity in Iranian patients with lymphoma. It seems that these differences could be due to ethnic factors.

Conclusion

The study showed high percentage of CD45 and CD20 seen in Iran’s positivity in Iranian patients with lymphoma. It seems that these differences could be due to ethnic factors.
